Detection and Categorization of Lung Cancer using Convolutional Neural Network

ABSTRACT

We developed a convolutional neural network that can detect abnormalities in lung using Computed Tomography (CT) scans and further categorize the abnormalities to benign, malignant adenocarcinoma and malignant squamous cell carcinoma. Our network is based on DenseNet, which utilizes dense connections between layers (dense blocks), so that all layers are connected. Because of all layers being connected, different layers can reuse features from previous layers which speeds up the process and make this network computationally efficient. To retrain this network we used CT images for 314 patients (over 900 CT images) consistent of 42 lung adenocarcinoma and 78 squamous cell carcinoma, 118 non cancer and 76 benign was acquired from the National Lung Screening Trial (NLST). These images were divided to two categories of Training and Validation with 70% being training dataset and 30% as validation dataset. We trained our network on Training dataset and checked the accuracy of our model using the validation dataset. Our model was able to categorize lung cancer with an accuracy of 88%. Afterwards we calculated the the confusion matrix, Precision (Sensitivity), Recall (Positivity) and F1 score for each category. This model is able to classify normal CT images with normal accuracy of 89% precision of 94% and F1 score of 93%. For benign nodules the Accuracy was 92%, precision 97% and F1 score 86%; for adenocarcinoma and squamous cell cancer the Accuracy was 98% and 93%, Precision 85% and 84%, and F1 score of 92% and 86.9%.

The relatively high accuracy of our model shows that convolutional neural networks can be a valuable tool for classification of lung cancer, especially in a small city or underdeveloped rural hospital settings and can play a role in achieving healthcare equality.
